

Appendix B

Emissions Inventory

This page intentionally blank.

Appendix B: Emissions Inventory

B.1 INTRODUCTION

Emissions inventories provide the best available estimates of the amount of pollutants and precursors being emitted into the atmosphere. Emissions inventories undergo continuous updating and changing to improve accuracy, respond to new scientific and engineering developments, and to address changes to laws and regulations. A snapshot of the inventory is used to develop air quality plans. At the time the snapshot is taken, it reflects the best inventory available. The “snapshot” used as the starting point for this plan is ARB’s PM 2.5 SIP Planning Projections, based on CEFS v1.06. This plan utilizes annual average and winter average daily inventories, with emissions presented as tons per day (tpd).

The inventories in this chapter are “planning inventories” used to study and propose control measures (Appendix I and Chapter 6), to track emissions for Rate of Progress (Chapter 8), to track ERCs (Appendix D), to establish motor vehicle conformity budgets for transportation planning (Appendix C), and to assist in demonstrating attainment (Chapter 10). In contrast, the “modeling inventory” provides day-specific information used as inputs for the regional model (Chapter 3 and the Modeling Protocol). While the planning and modeling inventories are based on the same basic information, they may have different cutoff dates for the inclusion of control measures (i.e., control measures adopted past the cutoff date are not reflected in the inventories and must be subtracted from the results of inventory runs and model runs).

This Appendix includes emissions inventories for the San Joaquin Valley Air Basin for the years 2005, 2009, 2010, 2011, 2012, 2013, and 2014. The baseyear (the year from which the inventory is projected forward and backward) for these inventories is 2002. The year 2005 has been included for control measure development and as the reference year for gridded modeling (see Chapter 3). The years 2009, 2010, 2011, 2012, 2013, and 2014 are possible PM2.5 compliance years for attainment. The years 2009 and 2012 are also RFP years (see Chapter 8). Results from EMFAC2007 have been incorporated into the mobile source portion of the inventories.

The tables in this appendix include:

- Table B-1 Directly emitted PM2.5, Annual and Winter Daily Averages
- Table B-2 NOx, Annual and Winter Daily Averages
- Table B-3 SO₂, Annual and Winter Daily Averages
- Table B-4 VOC, Annual and Winter Daily Averages
- Table B-5 Ammonia, Annual and Winter Daily Averages

The December 2007 Draft 2008 PM2.5 Plan contained tables of ARB and District adjustments for methodology revisions and control measures adopted between May 2005 and December 2006. This information has now been incorporated into the

baseline inventory, so adjustment tables have been removed. Tables B-1 through B-5 are followed by an overview of emissions inventory calculations and revisions.

B.2 EMISSIONS INVENTORY TABLES

B.3 EMISSIONS INVENTORY CALCULATIONS AND REVISIONS

Emissions are estimated in a variety of ways. Some point and mobile sources may have emissions source tests or continuous emissions monitoring, which can provide direct tabulation of emission rates. Data from source-specific emission tests or continuous emission monitors are usually preferred for estimating a source's emissions because those data provide the best representation of the source's emissions.

Typically, the mobile source inventory is based on population, activity rates, fuel specifications, and emissions of typical vehicles. For area sources, estimates are made based on 'surrogate' data that is assumed to be proportional to emissions, such as population, employment, economic data or some type of human activity. If no emissions data are available for a particular source, the District may send a survey to businesses that are identified as producing emissions from that source. The survey typically requests data that are used to estimate emissions. Each of the local air districts estimates the emissions for the stationary sources within its jurisdiction.

Emissions from natural sources are typically estimated by conducting a scientific study. ARB estimates emissions of biogenic volatile organic compounds (BVOCs) from vegetation for natural areas, crops, and urban vegetation. BVOC emissions are functions of the species leaf mass, emission factors, temperature, and light conditions. Other pollutants (e.g. NOx) also have biogenic sources.

B.3.1 Emission Factors and Emission Equations

The general equation for emission estimation is:

$$E = A \times EF \times (1-ER/100)$$

where:

E = emissions

A = activity rate

EF = emission factor

ER = overall emission reduction efficiency, percent

An emission factor relates the quantity of a pollutant emitted into the atmosphere to an activity associated with the pollutant's release. Such factors may be used in equations to estimate emissions from a process where source specific data is not available. Emission factors are typically expressed as the weight of pollutant divided by a unit weight, area, volume, distance, or duration of the activity emitting the pollutant. In most cases, these factors are simply averages of all available data of acceptable quality, and are generally assumed to be representative of long-term averages for all facilities in the source category. EPA publishes emission factors for many emissions categories in the document entitled AP-42.

Once an emission factor is determined, the next step is to determine the population (number of sources) and extent of each source. Population data is collected directly and indirectly. For example, vehicle registration data are gathered by the state. Stationary sources must obtain a permit from the District; therefore, populations of permitted equipment are directly obtained and are reasonably accurate. The number of fireplaces is not reported and must be estimated indirectly using housing statistics and surveys. Each source category has its own methodology.

The next step is to determine an activity rate. Activity data is reported in hours of operation, gallons of fuel used, miles traveled, and other units. Stationary sources of emissions permitted by the District are required to report actual emissions to ensure that they remain below their emission limits. This provides detailed activity data that is used in the emissions inventory. In other cases, facility operators can inform the District of their actual production figures or fuel burned. A survey is often carried out to determine usage rates.

B.3.2 Emissions Inventory Updates

The District, in cooperation with the ARB, is committed to continually updating the emissions inventory as research, emission factor updates, and other information become available. When emissions data change dramatically, the District is committed to revising the inventory and ensuring that any impact is reflected in the control strategy and the attainment demonstration.

The District re-evaluates the emissions inventory on a regular basis to ensure that the inventory is accurate and current. Major point sources are typically re-evaluated every year. Area sources are scheduled to be re-evaluated every one to five years. Seventy-five area source categories were updated during the period from 2003 to 2006.

The District updates emissions growth estimates on a periodic basis. Ten source categories are being examined in 2006 to reevaluate growth trends. The District also revises emissions estimates based on the effects of District prohibitory rules on an emissions source category. Approximately sixty-eight District prohibitory rules will be examined in 2006 to evaluate emissions controls and the effect of the rule requirements on the emissions inventory.
